Genetic Research. The red squirrel population on Anglesey has been bolstered with a series of reintroductions. Hair samples were collected from many animals that were used in the release program and genetic profiles were created. These studies revealed that the reintroduction projects involved a genetically rich and diverse range of animals.

L.O. 1.9 M.C. Question: Analysis of forelimb anatomy of human, bats, and whales shows that humans and bats, and whales shows that humans and bats have fairly similar skeletal structures, while whales have diverged considerably in the shapes and proportions of their bones. However, analysis of several genes in the species suggests that all three diverged from a common ancestor at about the same time.

are applied for the first time to rodent phylogenetics. Parsimony, likelihood, and Bayesian analyses of the separate gene regions and combined data reveal five major lineages and refute the conventional elevation of the flying squirrels (Pteromyinae) to subfamily status. Then the probability of getting a gene predisposing the squirrel to be white on the first draw would be p . But each squirrel gets a second draw. Assuming that the removal of an allele from the gene pool does not significantly change the frequencies, the same probabilities would apply on the second draw.

Segregational analysis indicated that the loss of the hr phenotype was due to a mutation in the PB2 gene itself. The nucleotide sequences of the PB2 gene of each of the four hr mutants revealed that a single amino acid substitution at position 627 (Glu-->Lys) was responsible for the restoration of the ability of the PB2 single gene reassortant to replicate in Madin-Darby canine kidney cells.

Abstract. Nucleotide sequences of a DNA fragment containing the long terminal repeat (LTR) of squirrel monkey retrovirus (SMRV) were determined. Sequence analysis showed that the SMRV LTR is 456 base pairs (bp) long and is bounded by 2-bp inverted repeats. Within the U3 region, there are two 43-bp repeats and two 42-bp repeats which are homologous...

Analysis applied to both populations modelled future levels of heterozygosity and allelic diversity. Sup-plementation of the remnant and reintroduced populations with translocated squirrels was simulated as a potential management tool; results support use of this strategy to reduce loss of diversity and increase survival.

Two notable subsections are "Selection for Human Birth Weight" and "Analysis of a Squirrel Gene Pool". What makes these two sub-sections noteworthy is the fresh approach they bring to the understanding of evolutionary mechanisms; most biology textbooks tend to present such mechanisms in a dry format thus making the topic less convincing to our students.

The frequency of the genotype, AA, or the homozygous dominant genotype, is expressed as p^2 in the Hardy-Weinberg equation. The frequency of AA is 36%. The frequency of Aa, or heterozygous, is expressed as $2pq$, and is 48%. The frequency of genotype aa, or homozygous recessive, is expressed as q^2 , and is 16%.
