The side chains point radially outward, and approximately every fourth unit is hydrogen-bonded to an adjacent one, which gives this structure its stability. Discovered by Linus Pauling, its name comes from its shape and from the fact that it was the first secondary polypeptide structure to be classified.

The earliest conception of the selective theory dates to Paul Ehrlich in 1900. In an attempt to explain the origin of serum antibody, Ehrlich proposed that cells in the blood expressed a variety of receptors, which he called "side-chain receptors," that could react with infectious agents and inactivate them.
